

Workplan for project A3: Motion Control of Unmanned Aerial Vehicle

Vilhelm Dinevik
Paula Carbó

February 9, 2018

1 Background

Unmanned aerial vehicles, also known as UAVs, are becoming nowadays more and more popular because they are small, cheap to produce, have low operating and maintenance cost, have great maneuverability, can perform steady flight operations and are able to enter high-risk areas without having to compromise human safety. Most applications that involve UAVs have been used in open areas without any obstacles and with a human in control of the UAV. But in recent years people have come up with more modern applications of UAVs that will need this UAVs to fly autonomously in densely populated areas, with a lot of other autonomous UAVs around, e.g. Amazon Prime Air delivery system, AltiGator drones services for inspection and data adquisition, or multi-UAVs used to deploy an aerial communications network. This places high demands on UAVs' obstacle avoidance capabilities for both moving and static obstacles.

There is many different manufacturers and a vast amount of different UAV models, all with different motors, weights, sensors and lift-to-weight ratio. To make a standard autonomous flight applicable to all these kinds of UAVs, a simple and easy-to-implement multi-UAV mathematical model, that will still be able to avoid obstacles with as few sensors as possible, is needed.

This project aims to study and develop a mathematical model of a quadrotor UAV and the available sensors in it. From the trajectory and pose tracking a state feedback controller will be designed. In order to facilitate the multi-UAV navigation potential fields or an A* algorithm will be used to make several quads fly to their goals mantaining collision avoidance with respect to other quads and obstacles. To check the validity of the models, a simulated test environment in MatLab filled with a random reasonable amount of static obstacles and autonomous UAVs will be used.

2 Work tree

3 Risks

Risks	P	C	R	Counter measure
Diseases in the group	2	2	4	Reactive: Rearrange workload Proactive: Nothing
Loss of documents and information	2	4	8	Reactive: recollect information again Proactive: Have bakups for everything, use Google Drive and GitHub
Running out of time	4	2	8	Reactive: Re-evaluate work plan and consult with supervisor Proactive: Have a good work plan, check on each other if we'll complete deadlines in time, check more the closer to the deadline
Bad communication with supervisor	2	2	4	Reactive: Send reminders if we get no answer in x amount of time. Ask supervisor how long should x be. Plan accordingly Proactive: Schedule meetings now (once a week for example) and modify these dates if there is no need to meet

4 Goals

Literature. Present a paper/combination of papers that describe the modelling of the UAVs, sensors and tracking. Observe how it is done in the community, categorize these papers and reflect on what is our contribution with respect to the rest.

Mathematical Model. Have a robust model for the kinematics and dynamics of the UAV, and its sensors.

Control. Be able to control the trajectory and stability of the UAV.

Multi-agent case. Apply and expand on the model and the control proposed for one UAV, but for a variable number of UAVs.

Simulation Verify that all the previous steps have been appropriately carried out so the main purpose of the project is achieved. Extract results.

5 Time line

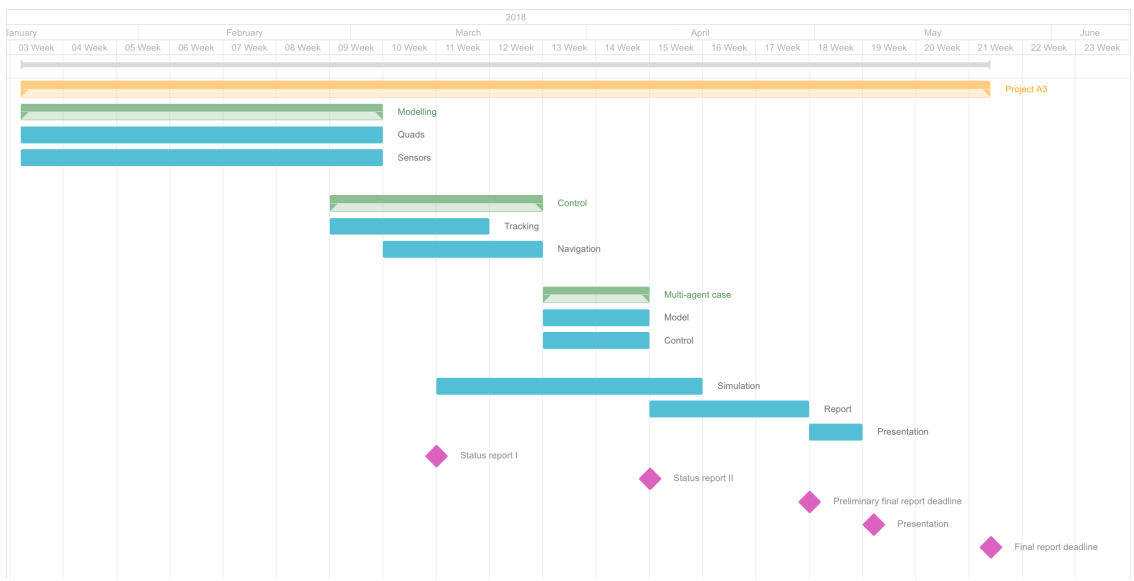

Figure 7: Timeline for the project
